Building a Secure Internet Data Center Network Infrastructure

The principal goal of this paper is to provide best practice information on designing and implementing secure networks in an Internet Data Center. I will focus on the expected threats and their methods of mitigation, rather than on "Put the firewall here, put the intrusion detection system there." I will begin with an overview of the architecture then follow with details of the specific modules that make up the actual network design.

MobileIron

EMM Strategy on the right track?
Know your security risks.

TAKE THE ASSESSMENT

A dark banner advertisement for MobileIron. On the left is the MobileIron logo, which consists of a red circle with a white 'M' and the word 'MobileIron' next to it. To the right of the logo is the text 'EMM Strategy on the right track? Know your security risks.' Further right is a green button with the text 'TAKE THE ASSESSMENT' in white. The background of the banner features a faint network diagram with nodes and lines.

As a consultant in a System Integration company, I am exposed to various network and system architecture, which varies from industries to industries. Generally, I would categorize the market into three major areas:

- i) Financial Industries – consists of financial industries like the banking sector, insurance and securities firms
- ii) Non-financial industries – consists of manufacturing companies, government sector and the transportation sector
- iii) Telecommunication industries – consists of telcos which provide Internet Access, phone and mobile access, as well as Data Center that provides hosting infrastructure

Each of these industries imposed different levels of risk in terms of its network and system architecture as well as its business requirements. In this paper, I will focus mainly on the telcos, which provide Internet Web hosting infrastructure to corporate customers.

The principle goal of this paper is to provide best practice information on designing and implementing secure networks in an Internet Data Center. I will focus on the expected threats and their methods of mitigation, rather than on “Put the firewall here, put the intrusion detection system there.” I will begin this document with an overview of the architecture, then details the specific modules that make up the actual network design. The first three sections of each module describe the traffic flows, key devices, and expected threats with basic mitigation diagrams. Detailed technical analysis of the design follows, along with more detailed threat mitigation techniques and migration strategies.

Architectural Components of an IDC Service Provider

The question is “What is an IDC”? An IDC is generally as a Data Center with facilities that provide hosting capabilities to any organizations who would like to host their servers, applications in the data center. The data center is equipped with video surveillance camera, on-site security officers, backup generators, biometrics sensors, fire suppression system and on-site management. Typically, an Internet Data Center provides the following services:

- i) Shared Web Hosting – In this service, the customer typically uses a portion of a server
- ii) Dedicated Server hosting – the customer uses the whole server and is normally a fully functional e-commerce software.
- iii) Co-location hosting – The customer has dedicated racking space to house their servers
- iv) Application hosting – The customer application is hosted at the IDC

The IDC architecture depicted below is pretty much based on Cisco’s recommendation in terms of building a scalable, robust and a secure network infrastructure:

Modular Approach

I would like to address the concept of an IDC center in a modular approach. Each of this module is essentially a functional module with application, network and security relationships between all the functional modules. With this approach, it allows an IDC to evaluate and implement security on a module by module basis, instead of attempting the complete the architecture in a single phase.

The figure below represents each of the functional modules. This high level overview shows the flow and functional relationship between the modules.

The diagram below represents a view of the modules within each functional block. Each of the modules will perform specific functions and will require specific security measures in conjunction with its functions. The diagram also represents an architectural view of a typical IDC network layout.

1) Management and Back-end Operations module

Essentially, the objective of having a management module is to ensure the management of all network and host devices within the IDC are being managed securely. Typically, these are the key devices in a Management module:

- Firewall Management console – this console is used to manage it's own firewall as well as customer's firewall
- Intrusion Detection System Console – the console is used to manage the network-based IDS and host-based IDS. It also serves as the central point for alert notification as well as management and configuration of all the IDS throughout the network. When firewalls are properly configured, they keep out most of the undesired traffic. However, in order to provide some level of access, firewalls have some tunnels left open that can be exploited by hackers. Packets that pass through these tunnels are typically not analysed by the firewall and allowed to pass through unexamined. This means that the internal devices have to be relied upon to protect the network for the allowed data streams. This is where intrusion detection systems (IDS) come into play, to compensate the above-mentioned weaknesses of firewalls. A complete IDS has two components. The first is a network-based system that monitors network traffic and detects attacks such as Distributed Denial of Service (DDoS) attacks based on recognised traffic signatures. The remaining component is a host-based system that monitors activities and events (execution of critical files, log-ons etc.) occurring within a host.
- Firewall – the function of this firewall is to control all incoming and outgoing traffic to/from the management network via specific ports.
- Network-based IDS – provides detection of attack that may successfully pass through the firewall and capture suspicious traffic within the module itself. The IDS is deployed in

Stealth Mode. Most IDS allows the configuration to monitor network traffic on one stealth interface and communicates with the IDS management network on another. This is called 'stealth mode' because the monitoring NIC does not have an IP address and is therefore invisible on the network. This configuration will further enhance the security of the IDS and the network.

- Syslog Server – this can be the central location for all the network devices as well as the host to send their respective logs to.
- Network management system – this server serves as the central SNMP monitoring for all devices.
- RADIUS/TACACS Server – it provides password management to network devices. Thus eliminating the need to store username and passwords on the device itself. It can also integrate with a Two-Factor authentication server to provide one-time password.
- Terminal Server – this server will be used to provide any configuration changes to devices
- Layer 2 switch – used to link up all the management module devices and preferably supports Private VLAN for added protection.

One of the most important tasks in the Management module is having proper logging and reporting capabilities for devices throughout the network. However, the challenge is always to read and maintain logs from all the devices in the network. Therefore, this management module can also be known as an out-of-band network. An OOB network is essentially a network where there is no production traffic. All the network devices will then send data and logs to the OOB network via direct connection. By having this network, managing logs and reporting becomes easier and more straightforward. All the logs can be directed to the Syslog server and in the event of any network related problems or security breach, the data and logs collected would be extremely useful for troubleshooting and analysis. The logs gathered from the syslog server can always complement the logs gathered from the IDS as well as the firewall for a more complete analysis

Another important area to look at is the alerting function. When an attack do occur, administrators will need to be notify and alerted. Thus, by utilizing in-built alerting plug-ins within the firewall/IDS or third party alert notification system such as Alarm Point, all appropriate alarms and alerts will be sent to the administrators via email, paging, SNMP traps and etc.

When all the alarms and alerts are gathered from multiple different sources, it is very important that the time of events are consistent and synchronized with each other. Thus, in order to synchronized the time, each of the network and host devices needs to be configured to point to a Network Time Protocol (NTP) server that will provide clocking to all the devices. This will ensure accurate and synchronized time among all devices.

Another important task is the segregation of duties and rights of operators and root administrators. It is always vital that to assign different privileges to different users. An operator will normally be assigned read-only rights and will not be allowed to do any configuration changes to a system. Daily tasks such as back-ups, monitoring and alerting are among the routines of an operator. Root administrators will have the administrative rights to the system. However, when an attack do happen, it is critical to know when is the last changes that took place. Therefore, proper Change Management Control will need to be in place to ensure that all system and configuration changes are properly documented.

Wherever possible, communication between all devices to the management module should be encrypted such as through the use of IPSEC, SSH or SSL encryption. The figure below shows a physical layout connectivity in the Management Module. Private VLAN is configured on the layer 2 switch to prevent hosts on the same subnet from communicating unless necessary.

2) Hosting Services Module

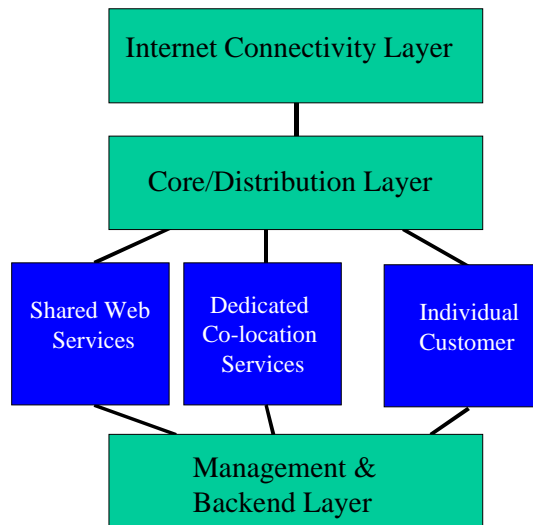

In this module, each IDC may deploy different ways in designing the architecture for the hosting network based on specific customer's requirement. In this paper, I will categorize the deployment into three categories:

- 1) Sharing of a single firewall amongst multiple different customers

In this scenario, the IDC will basically host a single firewall to protect multiple customers. However, this solution will only cater for a few basic services that will be allowed through the firewall itself. There are two ways to deploy this as well. The first will be connecting each customer to a different firewall subnet. In this case, the firewall will have multiple network interface cards to cater for each of the customers network. The second option is to connect the customer's network to a Layer 3 switch and assign individual VLAN to each of the customer. The switch will then be connected to the external firewall. Proper access control list will be implemented on the switch to prevent hosts within the switch to communicate with each other.
- 2) Customer having their own dedicated firewall and IDS

This is especially true for co-location customers whereby the customer will host their servers in a dedicated rack. In a single rack, all the servers are protected by a dedicated firewall and IDS is also deployed to provide better security.
- 3) No added security devices

The customer will host their servers without any security devices like firewall or IDS.

In this module, there are a host of threats and risks that the IDC will have to undertake. Among the threats are:

- **Operating system and application layer attacks**
 This attack can range from attack on the OS itself to attack to the application layer of the system. This is done by exploiting vulnerabilities and loopholes in the server itself. Apart from this, another form of common attack are virus attacks. The IDC or the customer themselves can deployed gateway anti-virus that intercepts HTTP, SMTP and FTP traffic traversing to and from the servers. By keeping up to date with the latest OS patches and fixes, the risk of getting compromised can be minimized. Host-based IDS can also be deployed to ensure that attacks to the host itself can be immediately detected and notified for immediate actions.
- **Unauthorized intrusion**
 This is by far the most common attack ranging from network probing to unauthorized port scanning. This threat can be very much mitigated to the use of proper access control and IDS. The network-based IDS deployed should have the capability to capture huge amount of traffic and be able to capture traffic across multiple VLANs. Generally, the types of traffic traversing in this module are WWW, FTP, SMTP and probably some Telnet traffic.
- **Packets sniffing**
 This can be easily limited through the use of switching technology.
- **Exploitation of trust relationship between hosts**
 The compromised of a server in the same subnet can lead to the exploitation of other servers within the subnet. Normally, in order to mitigate the threat of a compromised device, proper filtering is implemented at the firewall, router or Layer 3 switches to prevent exploitation from a compromised server. However, in a network within the same subnet, any host within the subnet can communicate with the rest of the hosts in the

subnet. Thus, Private VLAN is implemented on the Layer 2 switch in order to prevent a compromised device from communicating with other hosts on the same subnet.

- IP spoofing

This can be stopped on the firewall itself. If it is a locally initiated spoofed attack, RFC 2827 filtering on the switch can also help to limit the threat.

All servers within this Hosting Module are generally overlooked in terms of security. Thus, in summary, deployment of network-based and host-based IDS, access control at different levels, private VLANs, strong passwords and up-to-date system administration will be able to prove a better countermeasure and response against external as well as internal attack.

3) ISP Connectivity Module

This module will consist of the distribution and core layer switches as well as the border routers connecting to the Internet. The threats in this module typically targets the border router, core switches as well as the network itself. Among the threats are:

1) Router exploit

Routers by itself can be exploited in many ways. Like servers, they too are vulnerable. In the Internet, the customer's edge router is probably the first visible object. It is the device that provides access to and from every network and if the router itself is not secure, it can easily be compromised. There are standard ways to harden and secure a router and in summary, these are the basic necessary steps in hardening a router:

- Password management
The best way to handle passwords is to store them on a TACACS+ or RADIUS authentication server. However, almost every router will still have a locally configured password for privileged access. Simple steps like having multi-tier passwords and encrypting the passwords will reduce the likelihood of the password being compromised
- Controlling access to the router. Cisco router for example may support access and connections via Telnet, rlogin, console port and others. Thus, controlling access to the router via these means will ensure that only authorized administrator is allowed to login to the router. Access to the router can also be enhanced through the use of two-factor authentication together with Terminal Access Controller Access Control System Plus (TACACS+) or RADIUS server.
- Locking down Simple Network Management Protocol (SNMP) access to a router
- Turning off unnecessary services if not required such as HTTP, TCP and UDP small services, Finger, CDP and NTP
- Proper logging of router events will facilitate troubleshooting and analysis in the event of network problem or security breach. This can be achieved by sending the router logs to a syslog server in the Management Module. Also, in order to ensure that the routers time are synchronized, all the routers in the network can be configured to point to a NTP server
- Configure anti-spoofing on the router will minimize the risk of a spoofed attack. Configuring anti-spoofing is normally done on the border router to prevent external spoofing attack.
- If the routing protocol used in the router supports authentication, it is best enable that as well. This can help in some of the attack based on routing information.

- Basic filtering and access control list can also be configured to limit only legitimate traffic through the router. The router can therefore act as the first layer of access control for traffic coming into the network.

2) Switches

As for switches, most of the methods in securing a router apply to switches as well. However, there are not as much of information available in a switch as compared to a router. Other than the above, there are a couple steps that can be taken in further securing a switch:

- Trunk settings on a port should be turned off if the port is not used as a trunk port. This will prevent a host receiving all traffic on a trunk port if the port is configured with trunk settings.
- Disable all unused ports to prevent any unauthorized use of the ports to gain access to the network resources
- VLAN number on a trunk port should not be used anywhere else in the switch. This will prevent packets tagged with the same VLAN as the trunk port from reaching another VLAN without crossing a Layer 3 device
- Configuring Private VLAN on a switch will provide added protection to the hosts residing on the switch. Once deployed, if there is a compromised host in the network, it will not be able to communicate with other systems

3) Network Exploit

This exploit normally targets to bring down a network by flooding the network with enormous amount of traffic, so much traffic that the entire network becomes congested and simply stop receiving anymore traffic. This causes a Denial of Service to the network, as legitimate traffic is now unable to access the network. Distributed Denial of Service attack is such an attack and when it is executed successfully, it cannot be stopped. Such an attack can only be mitigated through cooperation with the ISP. The ISP can limit the amount of traffic flooding the customer's network by enabling rate-limiting feature on its router. Once the traffic exceeds a certain threshold, the traffic will be dropped.

At the customer border router, this rate-limiting feature can also be enabled to provide additional layer of control against the Ddos attack

Sample Router Configurations

Here are the basic configuration options present on nearly all routers in the SAFE lab:

```
! turn off unnecessary services
!
no ip domain-lookup
no cdp run
no ip http server
no ip source-route
no service finger
no ip bootp server
no service udp-small-s
no service tcp-small-s
!
```

```
!turn on logging and snmp
!
service timestamp log datetime localtime
logging 192.168.253.56
logging 192.168.253.51
snmp-server community Txo~QbW3XM ro 98
!
!set passwords and access restrictions
!
service password-encryption
enable secret %Z<)|z9~zq
no enable password
no access-list 99
access-list 99 permit 192.168.253.0 0.0.0.255
access-list 99 deny any log
no access-list 98
access-list 98 permit host 192.168.253.51
access-list 98 deny any log
line vty 0 4
access-class 99 in
login
password 0 X)[^j+#T98
exec-timeout 2 0
line con 0

line con 0  
login authentication no_tacacs
```

Sample Switches Configuration

Here is the base security configuration present on nearly all CAT OS switches in the SAFE lab. IOS switches use a configuration nearly identical to the router configuration.

```
!  
!Turn on NTP  
!  
set timezone PST -8  
set summertime PST  
set summertime recurring  
set ntp authentication enable  
set ntp key 1 trusted md5 -UN&/6[oh6  
set ntp server 192.168.254.57 key 1  
set ntp client enable  
!  
! turn off un-needed services  
!  
set cdp disable  
set ip http server disable  
!  
!turn on logging and snmp  
!  
set logging server 192.168.253.56  
set logging server 192.168.253.51  
set logging timestamp enable  
set snmp community read-only Txo~QbW3XM  
set ip permit enable snmp  
set ip permit 192.168.253.51 snmp  
!  
!Turn on AAA  
!  
set tacacs server 192.168.253.54 primary  
set tacacs key SJj)j~t]6-  
set authentication login tacacs enable telnet
```

```

set authentication login local disable telnet
set authorization exec enable tacacs+ deny telnet
set accounting exec enable start-stop tacacs+
set accounting connect enable start-stop tacacs+
!
!set passwords and access restrictions
!
set banner motd <c>
This is a private system operated for and by Cisco VSEC BU.
Authorization from Cisco VSEC management is required to use this system.
Use by unauthorized persons is prohibited.
<c>
